

CPS Project Insecure Edge Counting for Control- Flow Integrity

Rocco Versace – m. 1138644 Alessandro Frullo – m. 1132704

Main Goal

Main Goal

 This project aims at counting the number of indirect jumps and indirect calls to be protected in RISC-V binaries, excluding the ones which can be proven safe

How can we verify if a jump is considered safe?

We need to retrieve the origin tree of the source operand of the target

```
MOV R8, #1
LSL R8, R8, #27
MOV R11, 0x200
MOV R4, 0x40
ADD R5, R8, R11
ADD R3, R4, R5
BX R3
```

Starting Point

Starting Point

- This project starts where previous research left off in "PROLEPSIS: Binary Instrumentation Tool for Control-Flow Integrity in ARM and RISC-V" https://webthesis.biblio.polito.it/secure/24598/1/tesi.pdf
- While the previous work focused on **static** analysis, there's room for enhancement in **dynamic** conditions in order to retrieve the targets of indirect jumps.
- For this project some benchmark have been run: https://github.com/embench/embench-iot.git

Instrumentation

Instrumentation

 Benchmarks were compiled and run with a Qemu RISC-V32 environment, obtaining the static assembly code of each program, together with their program counter dynamic record

• The data obtained from the benchmarks were then processed with *Python* scripts

Obtaining assembly

riscv64-unknown-elf-objdump -D -S -M numeric main > main_DSnum.log

```
Disassembly of section .text:

Instructions classification

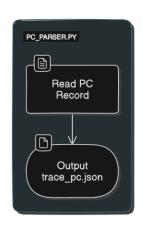

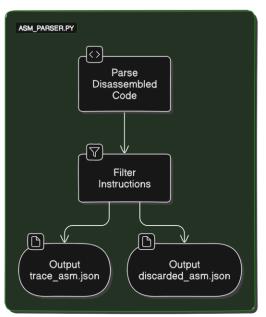

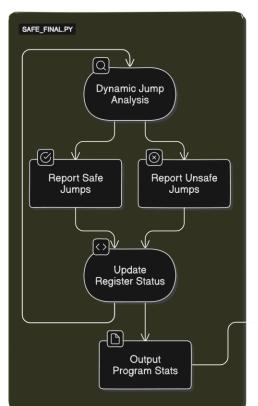

Program Flow

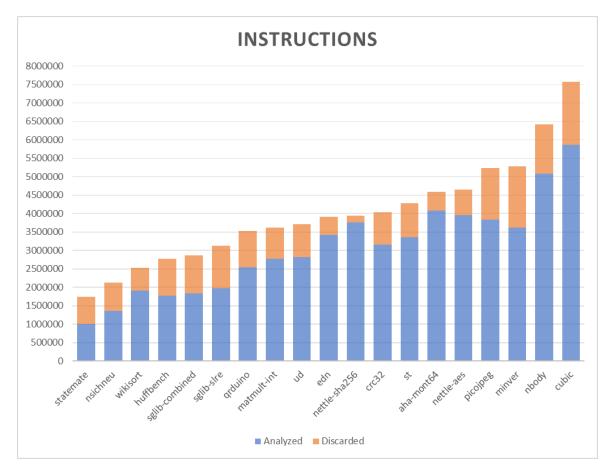

Results

Results

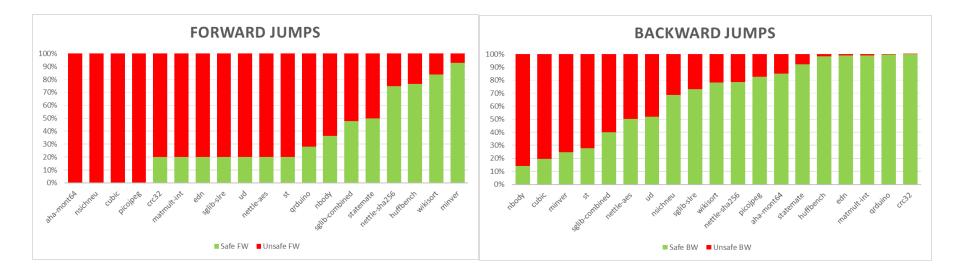

On average, 75% of instructions are analyzed and 25% are discarded:

- nettle-sha256: 95% of instructions are analyzed due to the need for many resultproducing instructions
- statemate: Only 58% of instructions are analyzed, with a large portion being nonresult-producing instructions

Results

- Forward jumps: On average, 94% of jumps are unsafe, and only 6% are safe.
- Backward jumps: The majority (94%) are safe.

The predominance of backward jumps is attributed to the frequent use of "ret" instructions (used to return from routines)

Results - statemate

Total jumps: 29498

Total fw jumps: 3935 (13.3%)
Safe fw: 1967 (50.0%)
Unsafe fw: 1968 (50.0%)

Balance between forward **safe** and **unsafe** jumps

```

A static analysis would have reported **2 safe jumps** and **9 unsafe jumps**, not highlighting the safeness balance observed in dynamic analysis of program execution.

Results - Forward jumps

In *wikisort* program the forward jumps turn out to be 84% **safe** compared to 16% **unsafe** forward jumps

This *jalr* (forward safe jump case) is executed about 7000 times, and a total of 47000 *jalr* are executed in the program with a similar construct

Results - Forward jumps

In the *nsichneu* program the forward jumps turn out to be 100% unsafe.

There are standard constructs, such as the one above, that are repeated several times in the code and lead to an unsafe jump

Results - Backward jumps

In *nbody*, **unsafe** backward jumps represent 86% of the total backward jumps

  101de:
                                 ∍ret
```

The instruction highlighted is executed many times (about 175000 out of a total of 175500 "ret") and the return address is never overwritten, leading to a backward safe jump

Conclusions

Conclusions

Reached objectives:

- Successfully compiled Embench IoT benchmark programs to retrieve the dynamic traces
- Successfully counted the number of insecure edges in executed RISC-V benchmark programs
- Results confirmed by patterns identified in the program trace
- Processed data stored in a CSV file, useful for further analysis
- First experience with Python code design

Future developments:

- Extend process to Mibench benchmark programs
- Refine the criteria chosen for defining safe edge and unsafe edge
